Troubleshoot

Pre-submit

F9. Create a few manual test cases. Calculate time and memory complexity. Check the limits. Be careful with overflows, constants, clearing mutitestcases, uninitialized variables.

Wrong answer

F9. Print your solution! Read your code. Check pre-submit. Are you sure your algorithm works? Think about precision errors and hash collisions. Have you understood the problem correctly? Write the brute and the generator.

Runtime error

F9. Print your solution! Read your code. F9 with generator. Memory limit exceeded.

Time limit exceeded

What is the complexity of your algorithm? Are you copying a lot of unnecessary data? (References) Do you have any infinite loops? Use arrays, unordered maps instead of vectors and maps.

Pragmas

- **#pragma** GCC optimize ("Ofast") will make GCC auto-vectorize loops and optimizes floating points better. It is not unexpected to see your floating-point error analysis go to waste.

- **#pragma GCC target ("avx2")** can double performance of vectorized code, but causes crashes on old machines.

- **#pragma GCC optimize("unroll-loops")** enables aggressive loop unrolling, which reduces the number of branches and optimizes parallel computation.

This is a highly detailed ASCII art representation of a large, symmetrical building. The structure is composed of various characters including slashes (/ and \), backslashes (\), dots (.), and vertical bars (|). The building features a central vertical axis with a series of horizontal bars and dots that create a sense of depth and structure. The overall shape is roughly rectangular with a slightly wider base and a narrower top, giving it a classical architectural appearance. The use of different symbols allows for the creation of various textures and patterns, such as the repeating '4' and '7' sequences in the lower central part, which might represent windows or decorative elements. The drawing is a single, continuous piece of art, with no separate components or a title.

dsu.hpp	f097c2, 31 lines
<pre>struct DSU { int n; VI p, sz; DSU(int _n = 0) { n = _n; p.resize(n); iota(ALL(p), 0); sz.assign(n, 1); } int find(int v) { if (v == p[v]) return v; return p[v] = find(p[v]); } bool unite(int u, int v) { u = find(u); v = find(v); if (u == v) return false; if (sz[u] > sz[v]) swap(u, v); p[u] = v; sz[v] += sz[u]; return true; } };</pre>	
fenwick.hpp	6a7a21, 20 lines
<pre>struct Fenwick { int n; VL t; Fenwick(int _n = 0): n(_n), t(n) {} void upd(int i, LL x) { for (; i < n; i = i + 1) t[i] += x; } LL query(int i) { LL ans = 0; for (; i >= 0; i = (i & (i + 1)) - 1) ans += t[i]; return ans; } };</pre>	
fenwick-lower-bound.hpp	730a06, 17 lines
<pre>int lowerBound(LL x) { LL sum = 0; int i = -1; int lg = 31 - __builtin_clz(n); while (lg >= 0) { int j = i + (1 << lg); if (j < n && sum + t[j] < x)</pre>	

```
        {
            sum += t[j];
            i = j;
        }
        lg--;
    }
    return i + 1;
}
```

Minimum on a Segment

Maintain two Fenwick trees with $n = 2^k$ — one for the original array and the other for the reversed array. If $n > 1$, you can use:
 $n = 1 \ll (32 - \text{__builtin_clz}(n - 1))$.

When querying for the minimum on the segment, only consider segments $[(i \& (i + 1)), i]$ that are completely inside $[l, r]$.

Add on a Segment

Maintain two Fenwick trees: tMult and tAdd.

To add x on the segment $[l, r]$, tMult.upd(l, x), tMult.upd($r, -x$), tAdd.upd($l, -x \cdot (l - 1)$), tAdd.upd($r, x \cdot r$).

$r \cdot \text{tMult.query}(r) + \text{tAdd.query}(r)$ is the sum on $[0, r]$.

min= and sum with Segment Tree

Store in each node: *max*, *cntMax*, *max2*, *sum*

In update check l, r conditions and:

- if ($val \geq max$) return;
- else if ($val > max2$) update this node;
- else go to left and right

You can do max= and += on segment at the same time. Time: $O(\log n)$. Each extra descent decreases number of diferent elements in segment.

treap.hpp
Description: uncomment in split for explicit key or in merge for implicit priority. Minimum and reverse queries.

```

lct.hpp

Description: Link-Cut Tree. Calculate any path queries. Change upd to maintain what you need. Don't use upd in push(). Calculate non commutative functions in both ways and swap them in push. cnt – number of nodes in current splay tree. Don't touch rev, sub, vsub. v->access() brings v to the top and pushes it; its left subtree will be the path from v to the root and its right subtree will be empty. Only then sub will be the number of nodes in the connected component of v and vsub will be the number of nodes under v. Change upd to calc sum in subtree of other functions. Use makeRoot for arbitrary path queries.

Usage: FOR (i, 0, n) LCT[i] = new snode(i); link(LCT[u], LCT[v]);

Time: $\mathcal{O}(\log n)$

Hierholzer’s algorithm

hierholzer.hpp
Description: Finds an Eulerian path in a directed or undirected graph. g is a graph with n vertices. $g[u]$ is a vector of pairs $(v, edge_id)$. m is the number of edges in the graph. The vertices are numbered from 0 to $n - 1$, and the edges - from 0 to $m - 1$. If there is no Eulerian path, returns $\{\{-1\}, \{-1\}\}$. Otherwise, returns the path in the form (vertices, edges) with vertices containing $m + 1$ elements and edges containing m elements. If you need an Eulerian cycle, check vertices[0] = vertices.back().

```
// 528807 for undirected

        pi[u] += d[u] - d[t];
}
return {flow, cost};
}
};
```

Maximum flow with minimum capacities

On the resulting graph, accumulate maximum flow in the following order:

- from S' to T'
- from S' to T
- from S to T'
- from S to T .

An $S - T$ flow that satisfies the minimum capacities exists if and only if, for all outgoing edges from S' and incoming edges to T' , the flow and capacity are equal.

Quadratic supermodular pseudoboolean optimization

$$\sum_i a_i x_i + \sum_i b_i \overline{x_i} + \sum_{i,j} c_{ij} x_i \overline{x_j} \rightarrow \min$$

$$c_{ij} x_i x_j = c_{ij} x_i - c_{ij} x_i \overline{x_j}$$

If $a_i \leq b_i$, add an edge from S to i of capacity $b_i - a_i$ and add a_i to the answer.

Otherwise, add an edge from i to T of capacity $a_i - b_i$ and add b_i to the answer.

Add an edge from i to j of capacity c_{ij} .

Add the $S - T$ minimum cut to the answer.

Matching tricks

Minimum cut

To find the min-cut, search from vertex S on unsaturated edges. Original edges from used vertices to unused ones are in the min-cut.

Minimum vertex cover

The vertex cover problem is not NP-complete in bipartite graphs. The minimum number of vertices required to cover all **edges** is equal to the size of the maximum matching. To reconstruct the minimum vertex cover, create a directed graph:

- matched edges from the right part to the left part
- unmatched edges from the left part to the right part.

Start traversal from unmatched vertices in the left part. The cover includes vertices from the matching:

- unvisited vertices in the left part
- visited vertices in the right part.

Maximum independent set

The independent set problem is not NP-complete in bipartite graphs. It is the complement of the minimum vertex cover.

Minimum edge cover

A minimum edge cover can be found in **any** graph. The minimum number of edges required to cover all vertices can only be determined in graphs without isolated vertices. By utilizing one edge in the matching, we cover two vertices, while any other vertices are covered using one edge for each.

DAG paths

In a DAG, you can find the minimum number of non-intersecting paths that cover all vertices. Duplicate vertices and create a bipartite graph with edges $u_L \rightarrow v_R$. Edges in the matching correspond to edges in the paths.

Dominating set

A dominating set for a graph is a subset D of V such that any vertex is in D , or has a neighbor in D . The dominating set problem is NP-complete **even on bipartite graphs**. It can be found greedily on a tree.

Dominator tree

dominator-tree.hpp

Description: Works for cyclic graphs. par – parent in dfs. p – parent in the DSU. val – vertex with the minimum sdом in dsu. dom – immediate dominator. sdом – semidominator, min vertex with alternate path. bkt – vertices with this sdом. dom[root] = -1. dom[v] = -1 if v is unreachable.

planar-graph.hpp
Description: Finds faces in a planar graph. Use addVertex() and addEdge() for
initializing the graph and addQueryPoint() for initializing the queries. After initial-
ization, call findFaces() before using other functions. getIncidentFaces(i) returns
the pair of faces (u, v) (possibly u = v) such that the i-th edge lies on the boundary
of these faces. getFaceOfQueryPoint(i) returns the face where the i-th query point
lies.

Newton’s method

Usable to find the solution of equation $F(Q) = 0$.

For example $F(Q) = x \cdot Q^2 + A - Q = 0$.

Newton’s method approximates the solution of the equation using the formula:

$$Q_{k+1} = Q_k - \frac{F(Q_k)}{F'(Q_k)}, \text{ where } F' = \frac{dF}{dQ}$$

Example of the derivative: $F'(Q) = 2 \cdot x \cdot Q - 1$.

Keep in mind that $|Q_k| = 2^k$.

FFT tricks

Two-dimensional FFT

The complexity is $\mathcal{O}(nm(\log n + \log m))$. The main problem is to resize the matrix. You must add non-empty vectors.

Divide-and-conquer FFT

Suppose we have the following DP relation:
 $f(t) = g(t) - \sum_{0 \leq u < t} f(u)h(t - u)$, where $g(t)$ and $h(t)$ are known and we want to compute $f(t)$. We can apply divide-and-conquer FFT.

Let $m = \lfloor \frac{l+r}{2} \rfloor$. We guarantee the following invariant conditions.

By the time we compute the values for the segment $[l, r)$, the following conditions are already met:

- The values for $[0, l)$ on the DP is already determined.
- The sum of contributions from $[0, l)$ through $[l, r)$ is already applied to the DP in $[l, r)$.

When calculate the values for the segment $[l, r)$ do:

- Calculate the values for the segment $[l, m)$ recursively.

- Calculate the contributions from $[l, m)$ to $[m, r)$.
- Calculate the values for the segment $[m, r)$ recursively.

Properties of the discrete Fourier transform

$$DFT(x)_k = \sum_{n=0}^{N-1} x_n \cdot e^{-i2\pi \frac{k}{N} n}$$

Let $x_n^R = x_{N-n \bmod N}$.

$$DFT(x^R) = \overline{DFT(x)}.$$

For real x , $DFT(x)^R = \overline{DFT(x)}$.

Interpolation

When x_0, x_1, \dots, x_d and y_0, y_1, \dots, y_d are given (where x_i are pairwise distinct), a polynomial $f(x)$ of degree no more than d such that $f(x_i) = y_i (i = 0, \dots, d)$ is uniquely determined.

Lagrange polynomial

Lagrange basis polynomial: $L_i(x) = \prod_{j \neq i} \frac{x - x_j}{x_i - x_j}$.

$$f(x) = y_0 L_0(x) + y_1 L_1(x) + \dots + y_d L_d(x).$$

Newton polynomial

Divided differences:

$$[y_i] = y_i$$

$$[y_i, y_{i+1}] = \frac{y_{i+1} - y_i}{x_{i+1} - x_i}$$

$$[y_i, \dots, y_j] = \frac{[y_{i+1}, \dots, y_j] - [y_i, \dots, y_{j-1}]}{x_j - x_i}$$

Newton basis polynomial: $N_i(x) = \prod_{j=0}^{i-1} (x - x_j)$.

$$f(x) = [y_0] N_0(x) + \dots + [y_0, y_1, \dots, y_d] N_d(x).$$

Linear recurrence

berlekamp-massey.hpp

$$k_3 = f(x_i + \frac{1}{2}h, y_i + \frac{1}{2}k_2h) \qquad k_4 = f(x_i + h, y_i + k_3h)$$

List of integrals

$$\int \frac{dx}{a^2 + x^2} = \frac{1}{a} \operatorname{arctg} \frac{x}{a} + C$$
$$\int \frac{dx}{a^2 - x^2} = \frac{1}{2a} \ln \left| \frac{x + a}{x - a} \right| + C$$
$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \arcsin \frac{x}{a} + C$$
$$\int \frac{dx}{\sqrt{x^2 + a}} = \ln \left| x + \sqrt{x^2 + a} \right| + C$$
$$\int \frac{dx}{\cos^2 x} = \operatorname{tg} x + C$$
$$\int \frac{dx}{\sin^2 x} = -\operatorname{ctg} x + C$$

Simpson’s rule

n – even number, $h = \frac{b-a}{n}$, $x_i = a + ih$

$$\int_a^b f(x)dx \approx \frac{h}{3} \left[f(x_0) + 4 \sum_{i=1}^{\frac{n}{2}} f(x_{2i-1}) + \right. \\ \left. + 2 \sum_{i=1}^{\frac{n}{2}-1} f(x_{2i}) + f(x_n) \right]$$

Vandermonde matrix

$$V = V(x_0, x_1, \dots, x_m) = \begin{bmatrix} 1 & x_0 & x_0^2 & \dots & x_0^n \\ 1 & x_1 & x_1^2 & \dots & x_1^n \\ 1 & x_2 & x_2^2 & \dots & x_2^n \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_m & x_m^2 & \dots & x_m^n \end{bmatrix}$$
$$V_{i,j} = x_i^j, \quad \det(V) = \prod_{0 \leq i < j \leq n} (x_j - x_i).$$

Hadamard matrix

$$H_1 = [1], \qquad H_{2^k} = \begin{bmatrix} H_{2^{k-1}} & H_{2^{k-1}} \\ H_{2^{k-1}} & -H_{2^{k-1}} \end{bmatrix}$$
$$\det(H_n) = \pm n^{\frac{n}{2}}$$

For a matrix M such that $|M_{ij}| \leq 1$, holds $|\det(M)| \leq n^{n/2}$.

Number theory

Calculation of $a^b \bmod m$
if $b \geq \phi(m)$, then value $a^b \equiv a^{[b \bmod \phi(m)] + \phi(m)} \pmod{m}$.

Generators

A generator exists only for $n = 1, 2, 4, p^k, 2p^k$ for odd primes p and positive integers k .

g is a generator modulo n if any number coprime with n can be represented as $[g^i \bmod n], 0 \leq i < \phi(n)$.

To find a generator:

- find $\phi(n)$ and $p_1, ..., p_m$ — the prime factors of $\phi(n)$

- g is generator only if $g^{\frac{\phi(n)}{p_j}} \not\equiv 1 \pmod n$ for each j
- check $g = 2, 3, 4, \dots, p - 1$

Wilson’s theorem

p is prime if and only if $(p - 1)! \equiv (p - 1) \pmod p$.

Quadratic residues

q is a quadratic residue modulo p if there exists an integer x such that $x^2 \equiv q \pmod p$. If p is odd prime then there exist $\frac{p+1}{2}$ residues (including 0).

Number theory functions

$$\begin{aligned} n &= p_1^{\alpha_1} \cdot \dots \cdot p_k^{\alpha_k} \\ \phi(n) &= \prod p_i^{\alpha_i-1} (p_i - 1) - \text{the number of coprimes} \\ F(n) &= \frac{n \cdot \phi(n)}{2} - \text{the sum of coprimes for } n > 1 \\ \mu(n) &= (-1)^k \text{ if } \max(\alpha_i) = 1, \text{ else } 0 \\ \sigma_k(n) &= \sum_{d|n} d^k \\ \sigma_0(n) &= \prod (\alpha_i + 1) \\ \sigma_{k>0}(n) &= \prod \frac{p_i^{(\alpha_i+1) \cdot k} - 1}{p_i^k - 1} \end{aligned}$$

Möbius

$$\begin{aligned} g(n) = \sum_{d|n} f(d) &\iff f(n) = \sum_{d|n} \mu(d) g\left(\frac{n}{d}\right) \\ M(n) = \sum_{k=1}^n \mu(k), \quad \sum_{d=1}^n M\left(\left\lfloor \frac{n}{d} \right\rfloor\right) &= 1 \\ \sum_{d|n} \phi(d) = n, \quad \sum_{d|n} \mu(d) &= [n = 1] \end{aligned}$$

Combinatorics
Binomials

$$\begin{aligned} \sum_{k=0}^n C_n^k &= 2^n & \sum_{k=0}^m C_{n+k}^k &= C_{n+m+1}^m \\ \sum_{m=0}^n C_m^k &= C_{n+1}^{k+1} & \sum_{k=0}^n (C_n^k)^2 &= C_{2n}^n \\ \sum_{j=0}^k C_m^j C_{n-m}^{k-j} &= C_n^k & \sum_{j=0}^m C_m^j C_{n-m}^{k-j} &= C_{n+1}^{k+1} \\ \sum_{k=0}^n C_{n-k}^k &= F_{n+1} \end{aligned}$$

Catalan numbers

$$C_n = \sum_{k=0}^{n-1} C_k C_{n-1-k} = \frac{1}{n+1} C_{2n}^n = C_{2n}^n - C_{2n}^{n-1}$$

1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786

Fibonacci numbers

$$\begin{aligned} F_1 = F_2 &= 1 & \gcd(F_m, F_n) &= F_{\gcd(n,m)} \\ F_n &= F_{n-1} + F_{n-2} & F_{n+1} F_{n-1} - F_n^2 &= (-1)^n \\ F_{n+k} &= F_k F_{n+1} + F_{k-1} F_n & F_{47} &\approx 2.9 \cdot 10^9 \\ F_n &= \frac{(\frac{1+\sqrt{5}}{2})^n - (\frac{1-\sqrt{5}}{2})^n}{\sqrt{5}} & F_{88} &\approx 1.1 \cdot 10^{18} \end{aligned}$$

Stirling numbers of the second kind

$S(n, k)$ – the number of ways to divide n element into k non-empty groups.
 $S(n, n) = 1, n \geq 0$
 $S(n, 0) = 0, n > 0$

$$S(n, k) = S(n - 1, k - 1) + S(n - 1, k) \cdot k.$$

$$B_n = \sum_{k=0}^n S(n, k) \text{ from } n = 0:$$

1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, 115975, 678570, 4213597, 27644437, 190899322, 1382958545, 10480142147, 82864869804,...

Generating functions

$$[x^i](1+x)^n = C_n^i \quad [x^i](1-x)^{-n} = C_{n+i-1}^i$$

$$C_\alpha^n = \frac{\alpha(\alpha-1)\dots(\alpha-n+1)}{n!}$$

$$\prod_{n=1}^\infty (1-x^n) = \sum_{k=-\infty}^\infty (-1)^k x^{\frac{k(3k-1)}{2}} \text{ (pentagonal number theorem)}$$

Hook length formula

A standard Young tableau is a filling of the n cells of the Young diagram with a permutation, such that each row and each column form increasing sequences. The **hook** $h_\lambda(i, j)$ is number of cells (a, b) in diagram such that $a = i$ and $b \geq j$ or $a \geq i$ and $b = j$.

The number of standard Young tableaux of shape λ :

$$f^\lambda = \frac{n!}{\prod h_\lambda(i, j)}$$

7	4	3	1
5	2	1	
2			
1			

A tableau listing the hook length of each cell in the Young diagram (4, 3, 1, 1)

Burnside’s lemma

Let G be a finite group that acts on a set X .

The *orbit* of an element x in X is the set of elements in X to which x can be moved by the elements of G . The orbit of x is denoted by $G \cdot x$:

$$G \cdot x = \{g \cdot x \mid g \in G\}.$$

For each g in G , let X^g denote the set of elements in X that are fixed by g (also said to be left invariant by g), that is, $X^g = \{x \in X \mid g \cdot x = x\}$. Burnside’s lemma asserts the following formula for the number of orbits, denoted $|X/G|$:

$$|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|.$$

Graphs

Prüfer sequence

At step i , remove the leaf with the smallest label and set the i -th element of the Prüfer sequence to be the label of this leaf’s neighbour. The Prüfer sequence of a labeled tree is unique and has length $n - 2$.

The number of spanning trees of K_n is n^{n-2} .
The number of spanning trees of $K_{L,R}$ number is $L^{R-1} \cdot R^{L-1}$.

Let $T_{n,k}$ be the number of labelled forests on n vertices with k connected components, such that vertices $1, \dots, k$ all belong to different components. $T_{n,k} = k \cdot n^{n-k-1}$.

The number of spanning trees in a complete graph K_n with the fixed degrees d_i is equal to: $\frac{(n-2)!}{\prod (d_i-1)}$

For a forest graph with connected components of sizes s_0, \dots, s_{k-1} , the number of ways to add edges to make a spanning tree is equal to: $n^{k-2} \cdot \prod s_i$

Chromatic polynomial

For a graph G , $\chi(G, \lambda) = \chi(\lambda)$ counts the number of its vertex λ -colorings. There is a unique polynomial $\chi(\lambda)$.

Deletion-contraction:

- The graph G/uv is obtained by merging u and v .
- The graph $G - uv$ is obtained by deleting the edge uv .
- $\chi(G, \lambda) = \chi(G - uv, \lambda) - \chi(G/uv, \lambda)$.

G is tree	$\chi(\lambda) = \lambda(\lambda-1)^{n-1}$
G is cycle C_n	$\chi(\lambda) = (\lambda-1)^n + (-1)^n(\lambda-1)$

Proposition. $\chi(\lambda)$ is equal to the number of pairs (σ, O) , where σ is any map $\sigma : V \rightarrow \{1, \dots, \lambda\}$ and O is an orientation of G , subject to the two conditions:

- The orientation O is acyclic.
- If $u \rightarrow v$ in O , then $\sigma(u) > \sigma(v)$.

Define $\bar{\chi}(\lambda)$ to be the number of pairs (σ, O) , where σ is any map $\sigma : V \rightarrow \{1, \dots, \lambda\}$ and O is an orientation of G , subject to the two conditions:

- The orientation O is acyclic.
- If $u \rightarrow v$ in O , then $\sigma(u) \geq \sigma(v)$.

Theorem. Suppose that $|V| = n$. Then for all non-negative integers λ holds:

$$\overline{\chi}(\lambda) = (-1)^n \chi(-\lambda)$$

Corollary. $(-1)^n \chi(G, -1)$ is equal to the number of acyclic orientations of G .

Kirchhoff’s theorem

Let G be a finite graph, allowing multiple edges but not loops.

The laplacian matrix L of G is the $n \times n$ matrix whose (i, j) -entry L_{ij} is given by

$$L_{ij} = \begin{cases} -m_{ij}, & \text{if } i \neq j, m_{ij} \text{ edges between } v_i \text{ and } v_j, \\ \deg(v_i), & \text{if } i = j. \end{cases}$$

Let L_0 denote L with the i -th row and column removed for any i . Then for a connected graph, $\det(L_0)$ equals the number of spanning trees of G .

Karp’s minimum mean-weight cycle algorithm

Let $G = (V, E)$ be a directed graph with weight function $w : E \rightarrow \mathbb{R}$, and let $n = |V|$. We define the **mean weight** of a cycle $c = \langle e_1, e_2, \dots, e_k \rangle$ of edges in E to be

$$\mu(c) = \frac{1}{k} \sum_{i=1}^k w(e_i).$$

Let $\mu^* = \min_c \mu(c)$, where c ranges over all directed cycles in G . We call a cycle c for which $\mu(c) = \mu^*$ a **minimum mean-weight cycle**.

Assume without loss of generality that every vertex $v \in V$ is reachable from a source vertex $s \in V$. Let $\delta_k(s, v)$ be the weight of a shortest path from s to v consisting of *exactly* k edges. If there is no path from s to v with exactly k edges, then $\delta_k(s, v) = \infty$.

$$\mu^* = \min_{v \in V} \max_{0 \leq k \leq n-1} \frac{\delta_n(s, v) - \delta_k(s, v)}{n - k}.$$

This can be computed in time $O(VE)$.

Planar graph properties

For a simple, **connected**, planar graph with v vertices, e edges and f faces, the following simple conditions hold for $v \geq 3$:

- Theorem 1. $e \leq 3 \cdot v - 6$.
- Theorem 2. If there are no cycles of length 3, then $e \leq 2 \cdot v - 4$.
- Theorem 3. $f \leq 2 \cdot v - 4$.
- Euler’s formula. $v - e + f = 2$.
- Theorem 4. $3 \cdot f \leq 2 \cdot e$.
- Theorem 5. The dual graph is also planar.
- Theorem 6. There exists a vertex v with $\deg(v) \leq 5$.

Dilworth’s theorem

A partially ordered set is a set S with a relation \leq on S satisfying:

1. $a \leq a$ for all $a \in S$ (reflexivity);
2. if $a \leq b$ and $b \leq a$, then $a = b$ (antisymmetry);
3. if $a \leq b$ and $b \leq c$, then $a \leq c$ (transitivity).

A chain is a subset of a set where each pair of distinct elements is comparable. An antichain is a subset of a set where every pair of elements is incomparable.

Dilworth’s theorem states that, in any finite partially ordered set, the **largest antichain** has the same size as the **smallest chain** decomposition. Here, the size of the antichain is its number of elements, and the size of the chain decomposition is its number of chains.

Geometry

Trigonometry formulas

$$\begin{aligned} \sin(v + w) &= \sin v \cos w + \cos v \sin w \\ \sin(v - w) &= \sin v \cos w - \cos v \sin w \\ \tan(v + w) &= \frac{\tan v + \tan w}{1 - \tan v \tan w} \\ \sin v + \sin w &= 2 \sin \frac{v+w}{2} \cos \frac{v-w}{2} \\ \cos v + \cos w &= 2 \cos \frac{v+w}{2} \cos \frac{v-w}{2} \end{aligned}$$

Ball formulas

$$\begin{aligned} a &= \sqrt{h \cdot (2R - h)} \\ V &= \pi \cdot h^2 \left(R - \frac{h}{3}\right) \end{aligned}$$

$$\begin{aligned} V &= \frac{1}{6} \pi h (3a^2 + 3b^2 + h^2) \\ R &= \sqrt{\frac{((a-b)^2 + h^2)((a+b)^2 + h^2)}{4h^2}} \end{aligned}$$

Triangle formulas

$$\begin{aligned} S &= \sqrt{p(p-a)(p-b)(p-c)} = \frac{abc}{4R} \\ m_a^2 &= \frac{2b^2 + 2c^2 - a^2}{4} (\text{median}) \\ w_a^2 &= \frac{bc((b+c)^2 - a^2)}{(b+c)^2} (\text{bisector}) \\ \frac{a}{\sin A} &= \frac{b}{\sin B} = \frac{c}{\sin C} = 2R \\ a^2 &= b^2 + c^2 - 2bc \cos A \end{aligned}$$

Monge’s theorem

There are three circles(balls) of different radii, for each pair of circles find the point of intersection of the external tangents. All three obtained points **lie on a line**. The point from the pair of the largest and the smallest **lies between** the other two.

Pick’s theorem

Suppose that a polygon has integer coordinates for all of its vertices. Let i be the number of integer points inside, and let b be the number of integer points on boundary. Then the area $S = i + \frac{b}{2} - 1$.

Ptolemy’s theorem

For a general quadrilateral $ABCD$ holds:
 $AB \cdot CD + AD \cdot BC \geq AC \cdot BD$.
Equality holds if and only if the quadrilateral is cyclic.

Ceva’s theorem

Given a triangle $\triangle ABC$ with a point P inside the triangle, continue lines AP , BP , CP to hit BC , CA , AB at D , E , F , respectively. Ceva’s theorem states that $\frac{AF}{FB} \cdot \frac{BD}{DC} \cdot \frac{CE}{EA} = 1$.

Simson line

Given a triangle $\triangle ABC$ and a point P on its circumcircle, the three closest points to P on lines AB , AC , and BC are collinear. The line through these points is the Simson line of P .

Euler line

For a general triangle, the orthocenter H , the centroid G , and the circumcenter O , in this order, lie on the same line (Euler line) and $\frac{|HG|}{|GO|} = \frac{2}{1}$.

Platonic solids

Polyhedron	Vertices	Edges	Faces
tetrahedron	4	6	4

octahedron	6	12	8
dodecahedron	20	30	12
icosahedron	12	30	20

Various (7)

Find n bits using $O(\frac{n}{\log n})$ sums

To find n bits x_0, \dots, x_{n-1} using $\approx 2.67 \cdot \frac{n}{\log_2(n)}$ sums of values in asked subsequences.

Define $Y + d$ as $\{y + d, \text{ for } y \in Y\}$.

Define f_k as maximum number of bits we can find using 2^k queries. We can make $f_{k+1} = 2 \cdot f_k + 2^k - 1$ using such queries:

- Ask sum of elements $[f_k, 2 \cdot f_k)$.
- Iterate through the first $2^k - 1$ queries Q_i , ask $Q_i \cup (Q_i + f_k)$ and $Q_i \cup [f_k, 2 \cdot f_k) \setminus (Q_i + f_k) \cup x_{2 \cdot f_k + i}$.
- Ask sum of elements $[0, f_{k+1})$.

If we have sums of queries $[f_k, 2 \cdot f_k)$, $Q \cup (Q + f_k)$ and $Q \cup [f_k, 2 \cdot f_k) \setminus (Q + f_k) \cup x$ as a , b and c respectively.

$$x = (c + b - a) \% 2, S(Q) = \frac{b+c-a-x}{2}, S(Q + f_k) = \frac{b+a-c+x}{2}.$$

k	0	1	2	3	4	5	10	13
2^k	1	2	4	8	16	32	$\approx 10^3$	$\approx 8 \cdot 10^3$
f_k	1	2	5	13	33	81	$\approx 5 \cdot 10^3$	$\approx 5 \cdot 10^4$

Matroid

In terms of independence, a finite matroid M is a pair (E, I) , where E is a finite set (called the ground set) and I is a family of subsets of E (called the independent sets) with the following properties:

1. The empty set is independent, i.e., $\emptyset \in I$;
2. Every subset of an independent set is independent, i.e., for each $A' \subseteq A \subseteq E$, if $A \in I$ then $A' \in I$;
3. If $A, B \in I$, and $|A| > |B|$, then there exists $x \in A \setminus B$ such that $B \cup \{x\} \in I$.

Matroid intersection

Matroids intersection of several matroids
 $M_1 = (X, I_1)$, $M_2 = (X, I_2)$, \dots , $M_k = (X, I_k)$ defined on the same ground set X represents “good” subsets as an intersection $I_1 \cap I_2 \cap \dots \cap I_k$. The task is to find a set of objects $S \subseteq X$ with maximum size such that $S \in (I_1 \cap I_2 \cap \dots \cap I_k)$.

Intersection of **three** or more matroids in **NP-complete** task.
However, the intersection of two matroids can be done in polynomial time $\approx O(|X|^2 + |X| \cdot F(|X|))$, where $F(|X|)$ is the time to build the graph below.

Starting from $S = \emptyset$ we can increase it’s size by one with following algorithm until maximum size. To do this, let’s build the following directed bipartite graph. The left part of this graph will contain all objects from S , while the right part will contain all **other** objects from X .

Consider objects from the right part of the graph such that adding them into S keeps independence in I_1 . Let’s paint these objects in green. Similarly, paint in a red color objects that keeps independence in I_2 .

Let’s add an edge from the left vertex u to the right vertex v when $S \setminus \{u\} \cup \{v\} \in I_1$. Symmetrically let’s add an edge from the right vertex v to the left vertex u when $S \setminus \{u\} \cup \{v\} \in I_2$.

Let’s find the path from some green vertex to some red vertex. Objects on the path are added or removed from the set S , respectively, objects from the right part are added and the left part is removed.

```

nim-product.hpp

Description: The Nim sum \oplus : $a \oplus b := \text{mex}(\{a' \oplus b \mid a' < a\} \cup \{a \oplus b' \mid b' < b\})$. The Nim product \otimes : $a \otimes b := \text{mex}(\{(a' \otimes b) \oplus (a \otimes b') \oplus (a' \otimes b') \mid a' < a, b' < b\})$. Let A be the set consisting of integers between 0 (inclusive) and 2^{2^n} (exclusive) (where n is an integer). Then the algebraic structure whose addition is \oplus and multiplication is \otimes forms a field. Such a field is called **Nimber**.
